- Conclusion.

In this paper, we consider ODE of the form

$$x'(t) = g(t, x(t)), \quad t \in [t_0, t_{end}], \quad x(0) = x^0$$
 (1)

where $x(t) \in \mathbb{R}^m$ and $g: D \subset \mathbb{R}^{m+1} \to \mathbb{R}^m$.

We assume:

the right-hand side of ODE (1) is sufficiently smooth;

In this paper, we consider ODE of the form

$$x'(t) = g(t, x(t)), \quad t \in [t_0, t_{end}], \quad x(0) = x^0$$
 (1)

where $x(t) \in \mathbb{R}^m$ and $g: D \subset \mathbb{R}^{m+1} \to \mathbb{R}^m$.

We assume:

- the right-hand side of ODE (1) is sufficiently smooth;
- there exists a unique solution x(t) to equation (1) on the interval $[t_0, t_{end}]$.

 Global Error Control is a desirable option of any ODE solver and sometimes necessary in practice.

- Global Error Control is a desirable option of any ODE solver and sometimes necessary in practice.
- However, Global Error Control can be very expensive and requires several numerical solutions over the integration interval [Skeel, 1986, 1989].

- Global Error Control is a desirable option of any ODE solver and sometimes necessary in practice.
- However, Global Error Control can be very expensive and requires several numerical solutions over the integration interval [Skeel, 1986, 1989].

Can we do better?

- Global Error Control is a desirable option of any ODE solver and sometimes necessary in practice.
- However, Global Error Control can be very expensive and requires several numerical solutions over the integration interval [Skeel, 1986, 1989].

Can we do better?

More precisely, can we control the global error for one integration?

It is well known that one integration is required to evaluate the global error and at least another one to control it. This is the principal difficulty of any global error control.

- It is well known that one integration is required to evaluate the global error and at least another one to control it. This is the principal difficulty of any global error control.
- Thus, it is clear that if we want to control the global error effectively (i.e. for one integration) we must not control it. This sounds contradictory.

- It is well known that one integration is required to evaluate the global error and at least another one to control it. This is the principal difficulty of any global error control.
- Thus, it is clear that if we want to control the global error effectively (i.e. for one integration) we must not control it. This sounds contradictory.

Who (or what) will control the global error?

A possible answer is the method itself!

A possible answer is the method itself!

More precisely, we control the local error. This can be done efficiently.

A possible answer is the method itself!

- More precisely, we control the local error. This can be done efficiently.
- \bullet The method ensures that True Error \approx Local Error at any grid point.

A possible answer is the method itself!

- More precisely, we control the local error. This can be done efficiently.
- The method ensures that True Error ≈ Local Error at any grid point.
- More formally, numerical schemes of order s considered here satisfy (τ_k is a size of the k-th step)

There are two implications of condition (2):

There are two implications of condition (2):

The methods considered in this paper belong to the class of quasi-consistent schemes because the orders of their local and global errors with respect to stepsize coincide.

There are two implications of condition (2):

- The methods considered in this paper belong to the class of quasi-consistent schemes because the orders of their local and global errors with respect to stepsize coincide.
- Moreover, we require additionally that the principal terms of the local and global errors coincide, i.e. these errors are asymptotically equal.

There are two implications of condition (2):

- The methods considered in this paper belong to the class of quasi-consistent schemes because the orders of their local and global errors with respect to stepsize coincide.
- Moreover, we require additionally that the principal terms of the local and global errors coincide, i.e. these errors are asymptotically equal.

That is why the usual local error control is expected to produce automatically numerical solutions satisfying user-supplied accuracy requirements for one integration.

Methods satisfying condition (2):

True Error
$$(k+1) = \text{Local Error}(k+1) + \mathcal{O}(\tau_k^{s+1}),$$
 (2)

are further refereed to as Doubly Quasi-Consistent.

HISTORY on Quasi-Consistent Integration:

HISTORY on Quasi-Consistent Integration:

 Skeel discovered the property of quasi-consistency in 1976.

HISTORY on Quasi-Consistent Integration:

- Skeel discovered the property of quasi-consistency in 1976.
- Skeel and Jackson found the first quasi-consistent methods among fixed-stepsize Nordsieck formulas in 1977.

HISTORY on Quasi-Consistent Integration:

- Skeel discovered the property of quasi-consistency in 1976.
- Skeel and Jackson found the first quasi-consistent methods among fixed-stepsize Nordsieck formulas in 1977.
- Kulikov and Shindin proved in 2006 that conventional Nordsieck formulas cannot exhibit the quasi-consistent behaviour on variable meshes because of the order reduction phenomenon.

HISTORY on Quasi-Consistent Integration (cont.):

HISTORY on Quasi-Consistent Integration (cont.):

 In 2009, Weiner et al. constructed actual variable-stepsize quasi-consistent numerical schemes in the family of explicit two-step peer formulas.

HISTORY on Quasi-Consistent Integration (cont.):

- In 2009, Weiner et al. constructed actual variable-stepsize quasi-consistent numerical schemes in the family of explicit two-step peer formulas.
- Kulikov proved in the same year that there exists no doubly quasi-consistent Nordsieck formula.

Thus, the first issue is:

Existence of Doubly Quasi-Consistent Numerical Schemes

Thus, the first issue is:

Existence of Doubly Quasi-Consistent **Numerical Schemes**

Further, we prove Existence of Doubly Quasi-Consistent Numerical Schemes in the family of fixed-stepsize s-stage Explicit Parallel Peer methods (EPP-methods)

Fixed-Stepsize EPP Methods

We deal further with numerical schemes of the form

$$x_{ki} = \sum_{j=1}^{s} b_{ij} x_{k-1,j} + \tau \sum_{j=1}^{s} a_{ij} g(t_{k-1,j}, x_{k-1,j}), \qquad (3)$$

$$i=1,2,\ldots,s,$$

Fixed-Stepsize EPP Methods

We deal further with numerical schemes of the form

$$x_{ki} = \sum_{j=1}^{s} b_{ij} x_{k-1,j} + \tau \sum_{j=1}^{s} a_{ij} g(t_{k-1,j}, x_{k-1,j}), \qquad (3)$$

 $i = 1, 2, \dots, s$, or in the matrix form

$$X_k = (B \otimes I_m)X_{k-1} + \tau(A \otimes I_m)g(T_{k-1}, X_{k-1})$$

where

$$T_k := (t_{ki})_{i=1}^s, \ X_k := (x_{ki})_{i=1}^s, \ g(T_k, X_k) := g(t_{ki}, x_{ki})_{i=1}^s,$$

$$A := (a_{ij})_{i,j=1}^s, \quad B := (b_{ij})_{i,j=1}^s.$$

We deal further with numerical schemes of the form

$$x_{ki} = \sum_{j=1}^{s} b_{ij} x_{k-1,j} + \tau \sum_{j=1}^{s} a_{ij} g(t_{k-1,j}, x_{k-1,j}), \qquad (3)$$

 $i = 1, 2, \dots, s$, or in the matrix form

$$X_k = (B \otimes I_m)X_{k-1} + \tau(A \otimes I_m)g(T_{k-1}, X_{k-1})$$

where

$$T_k := (t_{ki})_{i=1}^s, \ X_k := (x_{ki})_{i=1}^s, \ g(T_k, X_k) := g(t_{ki}, x_{ki})_{i=1}^s,$$

$$A := (a_{ij})_{i,j=1}^s, \quad B := (b_{ij})_{i,j=1}^s.$$

<u>DEFINITION 1:</u> The peer method (3) is consistent of *order p* if and only if the following order conditions hold:

$$\mathcal{AB}_i(l) := c_i^l - \sum_{j=1}^s \left(b_{ij} (c_j - 1)^l + l \, a_{ij} (c_j - 1)^{l-1} \right) = 0, \ l \le p.$$

<u>DEFINITION 1:</u> The peer method (3) is consistent of *order p* if and only if the following order conditions hold:

$$\mathcal{AB}_i(l) := c_i^l - \sum_{j=1}^s \left(b_{ij} (c_j - 1)^l + l \, a_{ij} (c_j - 1)^{l-1} \right) = 0, \ l \le p.$$

THEOREM 1: The peer method (3) of order p is doubly quasi-consistent if and only if its coefficients a_{ij} , b_{ij} and c_i satisfy the following conditions:

$$\mathcal{AB}(l) = 0, \quad l = 0, 1, \dots, p - 1,$$

$$B \cdot \mathcal{AB}(p) = 0, \ B \cdot \mathcal{AB}(p+1) = 0, \ A \cdot \mathcal{AB}(p) = 0.$$

With the use of Theorem 1, we yield the following doubly quasi-consistent EPP-method (3) presented by its coefficients:

$$A = \begin{pmatrix} \frac{89}{144} & \frac{23}{48} & -\frac{5}{36} \\ -\frac{133}{144} & \frac{29}{48} & \frac{55}{36} \\ -\frac{37}{144} & \frac{41}{48} & \frac{10}{9} \end{pmatrix},$$

$$B = \begin{pmatrix} \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \end{pmatrix}, \quad c = \begin{pmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{pmatrix}.$$

With the use of Theorem 1, we yield the following doubly quasi-consistent EPP-method (3) presented by its coefficients:

$$A = \begin{pmatrix} \frac{89}{144} & \frac{23}{48} & -\frac{5}{36} \\ -\frac{133}{144} & \frac{29}{48} & \frac{55}{36} \\ -\frac{37}{144} & \frac{41}{48} & \frac{10}{9} \end{pmatrix},$$

$$B = \begin{pmatrix} \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{19} & \frac{1}{2} & -\frac{1}{9} \end{pmatrix}, \quad c = \begin{pmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{pmatrix}.$$

This is a 3-stage explicit parallel peer method of order 2.

TRUE ERROR EVALUATION: Having used an embedded peer method (3) with coefficients A_{emb} , B_{emb} and c, we arrive at the error evaluation scheme of the form

$$\Delta_1 X_k = ((B_{emb} - B) \otimes I_m) X_{k-1}$$

$$+ \tau ((A_{emb} - A) \otimes I_m) g(T_{k-1}, X_{k-1})$$

$$(4)$$

where $\Delta_1 X_k$ denotes the principal term of the true error of the doubly quasi-consistent peer method and X_{k-1} implies the numerical solution computed by the same peer method. The global error estimation formula (4) is cheap.

THEOREM 2: Let the peer method (3) be doubly quasi-consistent and of order p. Then formula (4) computes the principal term of its true error at grid points if and only if the coefficients A_{emb} , B_{emb} and c of the embedded peer method satisfy the following conditions:

$$\mathcal{AB}(l)_{emb} = 0, \ l = 0, 1, \dots, p, \quad B_{emb} \cdot \mathcal{AB}(p) = 0$$

where the vectors $\mathcal{AB}(l)_{emb}$, $l=0,1,\ldots,p$, are calculated for the coefficients of the embedded formula (3) and the vector $\mathcal{AB}(p)$ is evaluated for the coefficients of the doubly quasi-consistent peer method in the embedded pair.

With the use of Theorem 2, the embedded peer method (3) for the doubly quasi-consistent peer scheme above is chosen to have the coefficients:

$$A_{emb} = \begin{pmatrix} -\frac{1}{18} & \frac{47}{96} & \frac{151}{288} \\ \frac{7}{18} & -\frac{35}{96} & \frac{341}{288} \\ \frac{58}{18} & -\frac{476}{96} & \frac{1069}{288} \end{pmatrix},$$

$$B_{emb} = \begin{pmatrix} \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{0} \end{pmatrix}, \quad c = \begin{pmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{pmatrix}.$$

With the use of Theorem 2, the embedded peer method (3) for the doubly quasi-consistent peer scheme above is chosen to have the coefficients:

$$A_{emb} = \begin{pmatrix} -\frac{1}{18} & \frac{47}{96} & \frac{151}{288} \\ \frac{7}{18} & -\frac{35}{96} & \frac{341}{288} \\ \frac{58}{18} & -\frac{476}{96} & \frac{1069}{288} \end{pmatrix},$$

$$B_{emb} = \begin{pmatrix} \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{9} \\ \frac{11}{18} & \frac{1}{2} & -\frac{1}{0} \end{pmatrix}, \quad c = \begin{pmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{pmatrix}.$$

This embedded formula is of classical order 2 and has the local error

GLOBAL ERROR CONTROL ALGORITHM:

- 1. k := 0, $\tau := \tau_{int}$; $(\tau_{int}, \gamma \in (0, 1))$ are set);
- 2. While $t_k < t_{end}$ do,

$$t_{k+1} := t_k + \tau$$
, compute X_{k+1} , $\Delta_1 X_{k+1}$;

3. If $\max_{k} \|\Delta_1 X_{k+1}\| > \epsilon_g$,

then
$$au:=\gamma \tau\left(\epsilon_g/\max_k\|\Delta_1 \tilde{X}_{k+1}\|\right)^{1/p}$$
, go to 1, else Stop.

TEST PROBLEM 1: Simple Problem

$$x_1'(t) = 2tx_2^{1/5}(t)x_4(t), \ x_2'(t) = 10t\exp\left(5(x_3(t) - 1)\right)x_4(t),$$

$$x_3'(t) = 2tx_4(t), \quad x_4'(t) = -2t\ln(x_1(t)),$$

where $t \in [0,3]$, $x(0) = (1,1,1,1)^T$.

TEST PROBLEM 1: Simple Problem

$$x_1'(t) = 2tx_2^{1/5}(t)x_4(t), \ x_2'(t) = 10t\exp\left(5(x_3(t) - 1)\right)x_4(t),$$

$$x_3'(t) = 2tx_4(t), \quad x_4'(t) = -2t\ln(x_1(t)),$$

where $t \in [0,3]$, $x(0) = (1,1,1,1)^T$.

The exact solution is well-known:

$$x_1(t) = \exp(\sin t^2), \quad x_2(t) = \exp(5\sin t^2),$$

 $x_3(t) = \sin t^2 + 1, \quad x_4(t) = \cos t^2.$

TEST PROBLEM 2: Restricted Three Body Problem

$$x_1''(t) = x_1(t) + 2x_2'(t) - \mu_1 \frac{x_1(t) + \mu_2}{y_1(t)} - \mu_2 \frac{x_1(t) - \mu_1}{y_2(t)},$$

$$x_2''(t) = x_2(t) - 2x_1'(t) - \mu_1 \frac{x_2(t)}{y_1(t)} - \mu_2 \frac{x_2(t)}{y_2(t)},$$

$$y_1(t) = ((x_1(t) + \mu_2)^2 + x_2^2(t))^{3/2}, y_2(t) = ((x_1(t) - \mu_1)^2 + x_2^2(t))^{3/2}$$

where $t \in [0,T]$, T=17.065216560157962558891, $\mu_1=1-\mu_2$ and

$$\mu_2 = 0.012277471$$
. The initial values are: $x_1(0) = 0.994$, $x_1'(0) = 0$,

$$x_2(0) = 0, x_2'(0) = -2.00158510637908252240.$$

TEST PROBLEM 2: Restricted Three Body Problem

$$x_1''(t) = x_1(t) + 2x_2'(t) - \mu_1 \frac{x_1(t) + \mu_2}{y_1(t)} - \mu_2 \frac{x_1(t) - \mu_1}{y_2(t)},$$

$$x_2''(t) = x_2(t) - 2x_1'(t) - \mu_1 \frac{x_2(t)}{y_1(t)} - \mu_2 \frac{x_2(t)}{y_2(t)},$$

$$y_1(t) = ((x_1(t) + \mu_2)^2 + x_2^2(t))^{3/2}, y_2(t) = ((x_1(t) - \mu_1)^2 + x_2^2(t))^{3/2}$$

where $t \in [0, T]$, T = 17.065216560157962558891, $\mu_1 = 1 - \mu_2$ and

 $\mu_2 = 0.012277471$. The initial values are: $x_1(0) = 0.994$, $x_1'(0) = 0$,

 $x_2(0) = 0, x_2'(0) = -2.00158510637908252240.$

Its solution-path is periodic.

NUMERICAL RESULTS for our Test Problems:

$$\epsilon_g = 10^{-04}.$$

DISADVANTAGE of THE STEPSIZE SELECTION:

DISADVANTAGE of THE STEPSIZE SELECTION:

The fixed-stepsize methods are not efficient!

DISADVANTAGE of THE STEPSIZE SELECTION:

The fixed-stepsize methods are not efficient!

Thus, the second issue is:
Accommodation of Doubly
Quasi-Consistent Numerical Schemes to variable meshes

DISADVANTAGE of THE STEPSIZE SELECTION:

The fixed-stepsize methods are not efficient!

Thus, the second issue is:
Accommodation of Doubly
Quasi-Consistent Numerical Schemes to variable meshes

This is to be done on the basis of:

The Polynomial Interpolation Technique

We introduce a variable grid with a diameter τ on the integration interval $[t_0, t_{end}]$ by

$$w_{\tau} := \{t_{k+1} = t_k + \tau_k, \ k = 0, 1, \dots, K - 1, \ t_K = t_{end}\}$$

where $\tau := \max_{0 \le k \le K-1} \{\tau_k\}$. It is clear that EPP-method (3) cannot be applied on w_{τ} .

We introduce a variable grid with a diameter τ on the integration interval $[t_0, t_{end}]$ by

$$w_{\tau} := \{t_{k+1} = t_k + \tau_k, \ k = 0, 1, \dots, K - 1, \ t_K = t_{end}\}$$

where $\tau := \max_{0 \le k \le K-1} \{\tau_k\}$. It is clear that EPP-method (3) cannot be applied on w_{τ} .

Let us consider that we have completed the (k-1)-th step of the size τ_{k-1} and computed the numerical solution $x_{k-1,i}^{k-1}$, $i=1,2,\ldots,s$.

We introduce a variable grid with a diameter τ on the integration interval $[t_0, t_{end}]$ by

$$w_{\tau} := \{t_{k+1} = t_k + \tau_k, \ k = 0, 1, \dots, K - 1, \ t_K = t_{end}\}$$

where $\tau := \max_{0 \le k \le K-1} \{\tau_k\}$. It is clear that EPP-method (3) cannot be applied on w_{τ} .

Let us consider that we have completed the (k-1)-th step of the size τ_{k-1} and computed the numerical solution $x_{k-1,i}^{k-1}$, $i=1,2,\ldots,s$. Further, we want to advance the next step of the size $\tau_{\mathbf{k}} \neq \tau_{\mathbf{k-1}}$.

At this point, we need two auxiliary grids:

$$w_{k-1} := \{t_{k-1,i}^{k-1} = t_k + (c_i - 1)\tau_{k-1}, i = 1, 2, \dots, s\}$$

and

$$w_k := \{t_{k-1,i}^k = t_k + (c_i - 1)\tau_k, i = 1, 2, \dots, s\}$$

where c_i , i = 1, 2, ..., s, are nodes of the fixed-stepsize EPP-method (3), which are considered to be distinct.

At this point, we need two auxiliary grids:

$$w_{k-1} := \{t_{k-1,i}^{k-1} = t_k + (c_i - 1)\tau_{k-1}, i = 1, 2, \dots, s\}$$

and

$$w_k := \{t_{k-1,i}^k = t_k + (c_i - 1)\tau_k, i = 1, 2, \dots, s\}$$

where c_i , $i=1,2,\ldots,s$, are nodes of the fixed-stepsize EPP-method (3), which are considered to be distinct. Now we utilize the interpolating polynomial $\mathbf{H_{k-1}^{s-1}(t)}$ of degree $\mathbf{s}-\mathbf{1}$ fitted to the data $\mathbf{x_{k-1,i}^{k-1}}$, $\mathbf{i}=\mathbf{1},\mathbf{2},\ldots,\mathbf{s}$, from the most recent step to accommodate this numerical solution to the new stepsize $\tau_{\mathbf{k}}$.

The scheme of computation is the following:

The scheme of computation is the following:

1. We calculate the new stage values $\mathbf{x}_{\mathbf{k-1,i}}^{\mathbf{k}}$, $\mathbf{i}=1,2,\ldots,\mathbf{s}$, for the grid $\mathbf{w_k}$ by the polynomial $\mathbf{H}_{\mathbf{k-1}}^{\mathbf{s-1}}(\mathbf{t})$.

The scheme of computation is the following:

- 1. We calculate the new stage values $\mathbf{x}_{\mathbf{k-1,i}}^{\mathbf{k}}$, $\mathbf{i}=1,2,\ldots,\mathbf{s}$, for the grid $\mathbf{w}_{\mathbf{k}}$ by the polynomial $\mathbf{H}_{\mathbf{k-1}}^{\mathbf{s-1}}(\mathbf{t})$.
- 2. We compute the numerical solution $\mathbf{x_{ki}^k}$, $\mathbf{i} = 1, 2, \dots, \mathbf{s}$, for the next step of the size τ_k by formula (3).

DEFINITION 2: The EPP-method of the form

$$t_{k-1,j}^k = t_k + (c_j - 1)\tau_k, \quad x_{k-1,j}^k = H_{k-1}^{s-1}(t_{k-1,j}^k), \tag{5a}$$

$$x_{ki}^{k} = \sum_{j=1}^{s} b_{ij} x_{k-1,j}^{k} + \tau_k \sum_{j=1}^{s} a_{ij} g(t_{k-1,j}^{k}, x_{k-1,j}^{k}), \qquad (5b)$$

where $H_{k-1}^{s-1}(t)$ is the interpolating polynomial of degree s-1 fitted to the numerical solution $x_{k-1,i}^{k-1}$, $i=1,2,\ldots,s$, from the previous step is called the *Explicit Parallel Peer method* with polynomial interpolation of the numerical solution (or, briefly, the interpolating EPP-method).

<u>THEOREM 3:</u> Let the EPP-method (3) with distinct nodes c_i be zero-stable. Then the interpolating EPP-method (5) is zero-stable if and only if the following condition holds:

$$\left\| \prod_{l=0}^{m} BH(\theta_{k+m-l}) \right\| \le R, \text{ for all } k \ge 0 \text{ and } m \ge 0 \tag{6}$$

where
$$h_{ij}(\theta_k) := \prod_{\substack{n=1, \\ n \neq j}}^{s} \frac{(c_i-1)\theta_k - c_n + 1}{c_j - c_n}, \quad i, j = 1, 2, \dots, s,$$

R is a finite constant and $\theta_k := \tau_k/\tau_{k-1}$ is the corresponding stepsize ratio of the grid w_{τ} .

<u>THEOREM 3:</u> Let the EPP-method (3) with distinct nodes c_i be zero-stable. Then the interpolating EPP-method (5) is zero-stable if and only if the following condition holds:

$$\left\| \prod_{l=0}^{m} BH(\theta_{k+m-l}) \right\| \le R, \text{ for all } k \ge 0 \text{ and } m \ge 0 \tag{6}$$

where
$$h_{ij}(\theta_k) := \prod_{\substack{n=1, \\ n \neq j}}^{s} \frac{(c_i-1)\theta_k - c_n + 1}{c_j - c_n}, \quad i, j = 1, 2, \dots, s,$$

R is a finite constant and $\theta_k := \tau_k/\tau_{k-1}$ is the corresponding stepsize ratio of the grid w_{τ} .

<u>DEFINITION 3:</u> The set of grids where the interpolating EPP-method (5) is stable is further referred to as *the set* $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids. Such grids satisfy the condition

$$0 \le \omega_1 < \theta_k < \omega_2 \le \infty, \ k = 0, 1, ..., K - 1,$$
 (7)

with constants ω_1 and ω_2 for which $\omega_1 \leq 1 \leq \omega_2$.

<u>DEFINITION 4:</u> The fixed-stepsize EPP-method (3) is said to be *strongly stable* if its propagation matrix B has only one simple eigenvalue at one and all others lie in the open unit disc.

<u>DEFINITION 4:</u> The fixed-stepsize EPP-method (3) is said to be *strongly stable* if its propagation matrix B has only one simple eigenvalue at one and all others lie in the open unit disc.

THEOREM 4: Let the underlying fixed-stepsize s-stage EPP-method (3) of consistency order $p \geq 0$ and with distinct nodes c_i be strongly stable. Then there exist constants ω_1 and ω_2 , satisfying (7), such that the corresponding s-stage interpolating EPP-method (5) is stable on any grid from the set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$.

<u>DEFINITION 5:</u> The fixed-stepsize EPP-method (3) is said to be *optimally stable* if its propagation matrix B has only one simple eigenvalue at one and all others are zero.

<u>DEFINITION 5:</u> The fixed-stepsize EPP-method (3) is said to be *optimally stable* if its propagation matrix B has only one simple eigenvalue at one and all others are zero.

THEOREM 5: Let the underlying fixed-stepsize s-stage EPP-method (3) with distinct nodes c_i be consistent of order $p \ge 0$. Suppose that its propagation matrix B satisfies

$$B = \mathbb{1}v^T \tag{8}$$

where $\mathbb{1}:=(1,1,\ldots,1)^T$ and $v:=(v_1,v_2,\ldots,v_s)^T$. Then the corresponding s-stage interpolating EPP-method (5) is stable on any grid from the set $\mathbb{W}_{0,\infty}^{\infty}(t_0,t_{end})$.

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \geq 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . Then the EPP-method (5) is convergent of order $\min\{p, s-1\}$, i.e. its global error satisfies

$$||X(T_k^k) - X_k^k|| \le C\tau^{\min\{p, s-1\}}, \quad k = 1, 2, \dots, K.$$

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \geq 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . Then the EPP-method (5) is convergent of order $\min\{p, s-1\}$, i.e. its global error satisfies

$$||X(T_k^k) - X_k^k|| \le C\tau^{\min\{p,s-1\}}, \quad k = 1, 2, \dots, K.$$

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \ge 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . Then the EPP-method (5) is convergent of order $\min\{p, s-1\}$, i.e. its global error satisfies $||X(T_k^k) - X_k^k|| \le C\tau^{\min\{p,s-1\}}, \quad k = 1, 2, \dots, K.$

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \geq 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . Then the EPP-method (5) is convergent of order $\min\{p, s-1\}$, i.e. its global error satisfies

$$||X(T_k^k) - X_k^k|| \le C\tau^{\min\{p,s-1\}}, \quad k = 1, 2, \dots, K.$$

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \geq 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . Then the EPP-method (5) is convergent of order $\min\{p, s-1\}$, i.e. its global error satisfies $||X(T_k^k) - X_k^k|| \le C\tau^{\min\{p,s-1\}}, \quad k = 1, 2, \dots, K.$

THEOREM 6: Let the right-hand side of ODE (1) be $\max\{p, s-1\}$ times continuously differentiable in a neighborhood of the exact solution and the stable EPP-method (3) with distinct nodes c_i be consistent of order $p \geq 1$. Suppose that the starting vector X_0^0 is known with an error of $\mathcal{O}(\tau^{\min\{p,s-1\}})$ and there exists a nonempty set $\mathbb{W}^{\infty}_{\omega_1,\omega_2}(t_0,t_{end})$ of admissible grids with finite parameter ω_2 . REMARK 1: Additionally, Theorem 6 says that double quasi-consistency condition (2) does not work in general to improve the convergence order of interpolating EPP-methods (5) because of the variable matrix $H(\theta_k)$ involved in numerical integration.

REMARK 1: Additionally, Theorem 6 says that **double quasi-consistency condition (2)** does not work in general to improve the convergence order of **interpolating EPP-methods (5)** because of the variable matrix $H(\theta_k)$ involved in numerical integration.

Further, we discuss how to accommodate double quasi-consistency to error estimation in interpolating EPP-methods.

REMARK 1: Additionally, Theorem 6 says that **double quasi-consistency condition (2)** does not work in general to improve the convergence order of **interpolating EPP-methods (5)** because of the variable matrix $H(\theta_k)$ involved in numerical integration.

Further, we discuss how to accommodate double quasi-consistency to error estimation in interpolating EPP-methods. We impose the following extra condition:

$$\tau/\tau_k \le \Omega < \infty, \quad k = 0, 1, \dots, K - 1, \tag{9}$$

where τ is the diameter of the grid. The set of grids satisfying (7) and (9) is denoted by $\mathbb{W}^{\Omega}_{\omega_1,\omega_2}(\mathbf{t_0},\mathbf{t_{end}})$.

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

THEOREM 7: Let ODE (1) be sufficiently smooth and the stable EPP-method (3) of order $p \geq 1$ and with distinct nodes c_i be doubly quasi-consistent. Suppose that another solution \bar{X}_k^k of order $\min\{p+1,s\}$ is known for a mesh w_τ and the polynomial $H_{k-1}^{s-1}(t)$ satisfies

$$p \le s - 1. \tag{10}$$

Then the interpolating EPP-method

$$X_k^k = (B \otimes I_m) \bar{H}_{k-1}^{s-1}(T_{k-1}^k) + \tau_k(A \otimes I_m) g(T_{k-1}^k, \bar{H}_{k-1}^{s-1}(T_{k-1}^k))$$

REMARK 2: If the more accurate numerical solution \bar{X}_{k}^{k} in the formulation of Theorem 7 is computed by another s-stage interpolating EPP-method (5) then condition (10) must be replaced with the more stringent one

$$p \le s - 2 \tag{11}$$

to retain the double quasi-consistency.

REMARK 2: If the more accurate numerical solution \bar{X}_{k}^{k} in the formulation of Theorem 7 is computed by another s-stage interpolating EPP-method (5) then condition (10) must be replaced with the more stringent one

$$p \le s - 2 \tag{11}$$

to retain the double quasi-consistency.

Notice that utilization of another s-stage interpolating EPP-method (5) is a natural requirement of the embedded method error estimation presented by formula (4).

REMARK 2: If the more accurate numerical solution \bar{X}_{k}^{k} in the formulation of Theorem 7 is computed by another s-stage interpolating EPP-method (5) then condition (10) must be replaced with the more stringent one

$$p \le s - 2 \tag{11}$$

to retain the double quasi-consistency.

- Notice that utilization of another s-stage interpolating EPP-method (5) is a natural requirement of the embedded method error estimation presented by formula (4).
- Thus, Remark 2 allows the same numerical solution \bar{X}_{k}^{k} to be used effectively in the doubly quasi-consistent method and in our error evaluation scheme as well.

CONSTRUCTION of EMBEDDED INTERPOLATING EPP-METHODS:

It follows from Theorem 7 and Remark 2 that the embedded s-stage underlying fixed-stepsize EPP-methods (3) must be of consistency orders s - 3 and s.

CONSTRUCTION of EMBEDDED INTERPOLATING EPP-METHODS:

- It follows from Theorem 7 and Remark 2 that the embedded s-stage underlying fixed-stepsize EPP-methods (3) must be of consistency orders s - 3 and s.
- the lower order method is to be doubly quasi-consistent of order s-2 and, hence, it is convergent of the same order on equidistant meshes.

CONSTRUCTION of EMBEDDED INTERPOLATING EPP-METHODS (cont.):

• We fit the interpolating polynomial to the numerical solution obtained from the higher order embedded formula and denote it further by $\bar{H}_{k-1}^{s-1}(t)$.

CONSTRUCTION of EMBEDDED INTERPOLATING EPP-METHODS (cont.):

- We fit the interpolating polynomial to the numerical solution obtained from the higher order embedded formula and denote it further by $\bar{H}_{k-1}^{s-1}(t)$.
- Our error estimation formula is presented by

$$\Delta_1 X_k^k = ((B_{emb} - B) \otimes I_m) \bar{X}_{k-1}^k + \tau_k ((A_{emb} - A) \otimes I_m) g(T_{k-1}^k, \bar{X}_{k-1}^k)$$

where A, B and A_{emb} , B_{emb} are coefficients of the EPP-methods of orders s-2 and s-1, respectively.

• In this way, we derive three pairs of embedded interpolating EPP-methods of orders s-2 and s-1 abbreviated further as IEPP23, IEPP34 and IEPP45.

- In this way, we derive three pairs of embedded interpolating EPP-methods of orders s-2 and s-1 abbreviated further as IEPP23, IEPP34 and IEPP45.
- All these numerical schemes satisfy the following conditions imposed on their coefficients:

$$B_{emb} = B = \mathbb{1}v^T$$
 and $c_{emb} = c$.

Thus, IEPP34 and IEPP45 are determine completely by fixing two matrices A, A_{emb} and two vectors c and v.

- In this way, we derive three pairs of embedded interpolating EPP-methods of orders s-2 and s-1 abbreviated further as IEPP23, IEPP34 and IEPP45.
- All these numerical schemes satisfy the following conditions imposed on their coefficients:

$$B_{emb} = B = \mathbb{1}v^T$$
 and $c_{emb} = c$.

Thus, IEPP34 and IEPP45 are determine completely by fixing two matrices A, A_{emb} and two vectors c and v.

IN THIS PAPER:

We have discussed the importance and power of double quasi-consistency for efficient integration of differential equations. We have shown here that the global error control can be done for one computation of the integration interval.

IN THIS PAPER:

- We have discussed the importance and power of double quasi-consistency for efficient integration of differential equations. We have shown here that the global error control can be done for one computation of the integration interval.
- At first, we have proved the existence of doubly quasi-consistent schemes in the class of fixed-stepsize explicit parallel peer methods.

IN THIS PAPER (cont.):

Then, we have explained how to accommodate the double quasi-consistency to variable-stepsize explicit parallel peer methods of interpolation type.

IN THIS PAPER (cont.):

- Then, we have explained how to accommodate the double quasi-consistency to variable-stepsize explicit parallel peer methods of interpolation type.
- Our experiments have confirmed that the usual local error control can be very powerful when applied in doubly quasi-consistent numerical schemes.
