We consider Nonlinear Volterra Integral Equations (NVIEs) of type

$$y(s) + \mu \int_a^s k(t, s) f(t, y(t)) (s - t)^\alpha (t - a)^\beta dt = g(s), \quad s \in (a, b], \quad (1)$$

where $\alpha, \beta > -1$, k, g and f are given functions, and y is the unknown. While equations of type (1) appear in numerous applications, this study specifically examines NVIEs as a reformulation (see, for example [1]) of equivalent nonlinear Fractional Differential Equations (FDEs). Here we introduce two Nyström-type methods based on product-type polynomial quadrature formulae. In particular, following an idea proposed in [2], the first formula is based on the polynomial approximation using the Generalized Bernstein polynomials, whereas, inspired by [3], the second is constructed using the Lagrange polynomials. The resulting Nyström methods are stable and convergent. Some examples of both NVIE and FDE numerical resolution are also given.
